The blades are aerodynamically designed and are securely attached at their base, an airfoil, to a rotor disk or "bucket." The bucket is typically provided with a number of circumferentially distributed dovetail slots which are designed to mate with projections or tongues on the base of the airfoil. Turbine buckets are hollow, cylindrical structures which have a number of rows of circumferentially arranged circumferential dovetail slots which are used to attach each row of blades. The buckets are structurally significant components of a turbine and should be sufficiently strong and durable to withstand repetitive strain and shock encountered during operation of the turbine. With proper maintenance and regular inspections, the buckets generally last the life of the turbine. Any problems with the buckets, however, can quickly lead to major repairs and the turbine can be out of operation for an extended period of time. All buckets are therefore subjected to inspections. These inspections must be performed by qualified personnel and also be conducted in accordance with the policies of the turbine owner or operator. Generally, buckets are first inspected visually by a qualified worker. Visual inspection for damaged buckets is effective but is very time consuming and generally only identifies buckets with a noticeable problem such as a cracked bucket or blade attachment. In many cases, the buckets are then removed from the turbine and examined using destructive testing techniques. These destructive testing techniques are often supplemented by x-ray and/or magnetic resonance imaging (MRI) scanning to assist in examining the bucket interior. With these destructive testing techniques, the integrity of each
